Java - Arrays

Sagar
Java Consultant

Arrays

- An *array* is an ordered list of values

An array of size N is indexed from zero to N-1

This array holds 10 values that are indexed from 0 to 9

Arrays . . .

- A particular value in an array is referenced using the array name followed by the index in square brackets
- For example, the expression

scores [2]

refers to the value **94** (the 3rd value in the array)

Initializer list

- An initializer list can be used to instantiate and fill an array in one step
- The values are delimited by braces and separated by commas
- Examples:

```
int[] units = {147, 323, 89, 933, 540,  
              269, 97, 114, 298, 476};
```

```
char[] letterGrades = {'A', 'B', 'C', 'D', 'F'};
```

Arrays – elements, index

- For example, an array element can be assigned a value, printed, or used in a calculation :

```
scores[2] = 89;
```

```
scores[first] = scores[first] + 2;
```

```
mean = (scores[0] + scores[1])/2;
```

```
System.out.println ("Top = " + scores[5]);
```

Arrays – declaration

- The **scores** array could be declared as follows:

```
int[] scores = new int[10];
```

- The type of the variable **scores** is **int[]** - an array of int type)
- Note that the array type does not specify its size, but each object of that type has a specific size
- The reference variable **scores** is set to a new array object that can hold 10 integers
- An array is an object, therefore all the values are initialized to default ones (**zero**) • • • •

Arrays – elements, index

- Some other examples of array declarations:

```
float[] prices = new float[500];
```

```
boolean[] flags;
```

```
flags = new boolean[20];
```

```
char[] codes = new char[1750];
```

Arrays – elements, index

- The iterator version of the `for` loop can be used when processing array elements

```
for (int score : scores)
    System.out.println (score);
```

- This is only appropriate when processing all array elements from top (lowest index) to bottom (highest index)

Arrays – Size, exceeding index limit

- Once an array is created, it has a fixed size
- An index used in an array reference must specify a valid element
- That is, the index value must be in range 0 to N-1
- The Java interpreter throws an **ArrayIndexOutOfBoundsException** if an array index is out of bounds
- This is called automatic *bounds checking*

Bounds Checking

- For example, if the array codes can hold 100 values, it can be indexed using only the numbers 0 to 99
- If the value of count is 100, then the following reference will cause an exception to be thrown:

```
System.out.println (codes[count]) ;
```

```
for (int index=0; index <= 100; index++)  
    codes[index] = index*50;
```

problem

Arrays – length – instance constant

- Each array object has a public constant(instance constant) called **length** that stores the size of the array
- It is referenced using the array name:

scores.length

- Note that **length** holds the number of elements, not the largest index

Char type

```
String st = "abcd";  
for(int i =0; i < st.length (); i++ ) {  
    char c = st.charAt (i);  
    System.out.print(c);  
    System.out.print(" ");  
    System.out.print((int) c);  
    System.out.print(" ");  
    System.out.println(c - 'a');
```

```
a 97 0 }
```

```
b 98 1
```

```
c 99 2
```

Float type

- The brackets of the array type can be associated with the element type or with the name of the array
- Therefore the following two declarations are equivalent:

```
float[] prices;
```

```
float prices[];
```

- The first format generally is more readable and should be used

Two Dimensional Arrays

- A *one-dimensional array* stores a list of elements
- A *two-dimensional array* can be thought of as a table of elements, with rows and columns

one
dimension

two
dimensions

Two Dimensional Arrays ...

- To be precise, in Java a two-dimensional array is an array of arrays
- A two-dimensional array is declared by specifying the size of each dimension separately:

```
int[][] scores = new int[12][50];
```

- A array element is referenced using two index values:

```
value = scores[3][6]
```

- The array stored in one row can be specified using one index

Two Dimensioned Array - Example

```
public static void main (String[] args) {  
    int[ ][ ] table = new int[5][10];  
  
    // Load the table with values  
    for (int row=0; row < table.length; row++)  
        for (int col=0; col < table[row].length; col++)  
            table[row][col] = row * 10 + col;  
  
    // Print the table  
    for (int row=0; row < table.length; row++) {  
        for (int col=0; col < table[row].length; col++)  
            System.out.print (table[row][col] + "\t");  
        System.out.println();  
    } // end of for  
} // end of main()
```

Result

0	1	2	3	4	5	6	7	8	9
10	11	12	13	14	15	16	17	18	19
20	21	22	23	24	25	26	27	28	29
30	31	32	33	34	35	36	37	38	39
40	41	42	43	44	45	46	47	48	49
